## Step 1: Setup

# Related

Arduino Ethernet Web Server  
([HACKED](#)) ([/id/Arduino-Ethernet-Web-Server-HACKED/](#)) by M. H. S.

connect arduino with  
ethernet ([/id/Connect-Arduino-With-Ethernet/](#))  
by LuckyS22

//id/E705SN7H05NT26/\

Setting it up is as simple as plugging the header pins from the shield into your Arduino.

Note that the Ethernet Shield sold at Radioshack is online compatible with Arduino Uno Rev. 3 boards (or later). It has too many pins to plug into earlier version Arduino boards.

advertisement

## Step 2: Shield Features

//id/EMK2BSQH05NOV09/\

The Ethernet Shield is based upon the W51000 chip, which has an internal 16K buffer. It has a connection speed of up to 10/100Mb. This is not the fastest connection around, but is also nothing to turn your nose up at.

It relies on the Arduino Ethernet library, which comes bundled with the

Run Ethernet shield on arduino [\(/id/Run-Ethernet-Internet-Devices-for-Home-Automation-Devices-for-Home-Automation/\)](#)

Arduino Web Server [\(/id/Arduino-Web-Server/\)](#)  
by diytransistor [\(/member/diytransistor/\)](#)

development environment.

There is also an on-board micro SD slot which enables you to store a heck-of-a-lot of data, and serve up entire websites using just your Arduino. This requires the use of an external SD library, which does not come bundled with the software. Using the SD card is not covered in this Instructable. However, it is covered in the Step 8 (<https://www.instructables.com/id/Arduino-Wireless-SD-Shield-Tutorial/step8/Prepare-the-SD-card/>) of the Wireless SD card instructable.

The board also has space for the addition of a Power over Ethernet (PoE) module, which allows you to power your Arduino over an Ethernet connection.

For a full technical overview, see the official Ethernet Shield (<http://arduino.cc/en/Main/ArduinoEthernetShield>) page.

### Step 3: Get Started

//file/EDB0VQYH05NBQWQ/\

//file/ETA0CMQH05Y7KE8/\

Plug the Arduino into your computer's USB port, and the Ethernet shield into your router (or direct internet connection).

Next, open the Arduino development environment. I highly recommend upgrading to Arduino 1.0 or later (if you have not done so already). This version of the software has built in DHCP support, and does not require manually configuring an IP address.

To figure out what IP address has been assigned to your board, open the DhcpAddressPrinter sketch. This can be found at:

File --> Examples --> Ethernet --> DhcpAddressPrinter

Once open, you may need to change the Mac address. On newer versions of the Ethernet shield, you should see this address on a sticker attached to the board. If you are missing a sticker, simply making up a unique mac address should work. If you are using multiple shields, make sure each has a unique mac address.

Once the mac address is properly configured, upload the sketch to your Arduino, and open the serial monitor. It should print out the IP address in use.

## Step 4: Server

You can use the Arduino Ethernet shield as a web server to load an HTML page or function as a chat server. You can also parse requests sent by a client, such as a web browser. The following two examples show how to use it to serve HTML pages, and parse URL strings.

One important thing to keep in mind is that you will have to enter your Arduino's IP address in both of the examples below in order for them to work.

The following code changes the web page served based on a button press:

```
/*
  Web Server Demo
  thrown together by Randy Sarafan

  A simple web server that changes the page that is served, triggered by a button press.

  Circuit:
  * Ethernet shield attached to pins 10, 11, 12, 13
  * Connect a button between Pin D2 and 5V
  * Connect a 10K resistor between Pin D2 and ground

  Based almost entirely upon Web Server by Tom Igoe and David Mellis

  Edit history:
  created 18 Dec 2009
```

To make this example code work, simply attach a button between pin D2 and 5V, a 10K resistor between pin D2 and ground, and then load the IP address of your Arduino into your web browser. The page should load with a black background. Press and hold the button, and then refresh the browser page. The site should now load with a white background.

The following code lights up an LED depending on the URL that is sent to the Arduino:

```
/*
  Web Server Demo
  thrown together by Randy Sarafan

  Allows you to turn on and off an LED by entering different urls.

  To turn it on:
  http://your-IP-address/$1

  To turn it off:
  http://your-IP-address/$2

  Circuit:
  * Ethernet shield attached to pins 10, 11, 12, 13
  * Connect an LED to pin D2 and put it in series with a 220 ohm resistor to ground
```

To make this work connect the positive lead an LED to pin D2, and the negative lead in series with a 220 ohm resistor to ground.

To turn on the LED enter this into your browser:  
http://**[YOUR IP ADDRESS HERE]**/\$1

To turn off the LED enter this into your browser:  
http://**[YOUR IP ADDRESS HERE]**/\$2

Note: You should obviously replace **[YOUR IP ADDRESS HERE]** with your IP address.

## Step 5: Client

U561EOL062HH05NP76W1

You can also use the Ethernet Shield as a client. In other words, you can use it to read websites like a web browser.

Websites have a lot of text both visible and hidden, which makes programming on the client side very tricky. Reading information from websites typically involves parsing a lot of strings. This is maddening, but worth it, if that is what you intend to do.

I was going to write some code to read Twitter messages, but such a code already exists as an example within the Arduino programmer. Instead, I simply modified it slightly to turn on an LED if a special message is read.

To make this work connect the positive lead an LED to pin D2, and the negative lead in series with a 220 ohm resistor to ground.

Don't forget to enter your own IP address into the code below, or it will not work.

Here is the code:

```
/*  
  Twitter Client with Strings  
  
  This sketch connects to Twitter using an Ethernet shield. It parses the XML  
  returned, and looks for <text>this is a tweet</text>  
  
  You can use the Arduino Ethernet shield, or the Adafruit Ethernet shield,  
  either one will work, as long as it's got a Wiznet Ethernet module on board.  
  
  This example uses the DHCP routines in the Ethernet library which is part of the  
  Arduino core from version 1.0 beta 1  
  
  This example uses the String library, which is part of the Arduino core from  
  version 0019.
```

Presumably you are going to want to read something other than the recent post on the RandyMcTester Twitter feed.

To read other Twitter feeds, change the following bit of text:

```
client.println("GET /1/statuses/user_timeline.xml?screen_name=[NEW  
TWITTER NAME HERE]&count=1 HTTP/1.1");
```

We have a be nice comment policy.  
Please be positive and constructive.

I Made it!

Have you set up the ip of the Ethernet shield? the ip  
should be same range as your PC's ip like

192.168.0.2 for PC

192.168.0.10 for shield.

And also some cheap W5100 shields has a problem with a resistor array situated near the RJ45 socket. It should be 510 instead of 511 (510hm instead of 510ohm)

The Arduino shield and the computer both have the same RJ45 connections. That is, the send and receive pins are on the same pin for both sender and receiver. If you connect them directly with a cable, the send pins match up and the receive pins match up and therefore you get no communications.

You either need an Ethernet hub/switch or a cross over cable that crosses over the Send and Receive pins. The hub/switch is definetly the easiest way to go and you can pick them up cheaply from amazon.

Just a thought, when you normally plug your Arduino board into your computer the usb cable supplies the power. Most ethernet does not support power over internet (POI), so unless you are also connecting to your PC using usb at the same time you will need to supply external power to your board.

If you already provided external power ignore this comment.

Let me first start by saying that I am a complete noob when it comes to anything  
Arduino. My kit hasn't even arrived in the mail yet so please go easy on me. :)

However, I have a question regarding this project. Specifically the RJ45  
Ethernet Shield. In your example you are using the RJ45 to interact with the  
Arduino via a website/internet, is it possible to use the Arduino + Shield to  
interact with a series of rocker switches via a 8 channel relay board? If so, I was  
thinking that it would make the installation of my project really clean being able  
to use the RJ45 cable between my Arduino and the switches that will be located  
perhaps 10-15 feet away.

Any and all help is appreciated.

how to access the ethernet shield from the outside  
of the local network - that is from the internet?

You need to port forward the IP and port you are using of the ethernet  
shield to the internet

This website may help: <http://portforward.com/> (<http://portforward.com/>)

I guess the local dynamic IP has to be changed, right..?

Yes if you are port forwarding the ethernet shield should have a static  
local IP. You can define the ethernet shield IP in the code.

<http://arduino.cc/en/Reference/EthernetIPAddress>  
(<http://arduino.cc/en/Reference/EthernetIPAddress>)

you can find your DNS servers, gateway, and subnet by typing *ipconfig /all* in a windows command line.

Make the ip of the ethernet shield any ip not currently used on you network. An easy way do do this is to take IP address listed in *ipconfig /all* and change the numbers after the last dot to *254* and put that in the *arduino code as its IP*.

Where to get that IP?

If you mean your public IP you can find that by visiting

<http://www.whatismyip.com/> (<http://www.whatismyip.com/>)

I have one of the Non-POE (power Over Ethernet) 5100's, and it does the same to me.. I think it's the 3.3V regulator trying to run the single chip, which is chewing-up massive wattage.. (even if it is being powered from the +5V regulator from the Arduino.) I've often wondered, if I could repower this off the 3.3V off an external power supply, but someone said that's a bad idea, as the back-feed could burn-out the regulator, and other chips switching between the 9 down to 5, and 5 down to 3.3, or even the USB to serial chip.

**alin.bartos (/member/alin.bartos)** ▶ Gelfling6 (/member/Gelfling6)

Reply

3 years ago

You need to supply the arduino and the shield with 7 or 7.5 v, you can use a dc-dc power regulator. I use a 12v power suply and a dc to dc regulator, who give me 7.5v and everything is fine.

Wow! a whole year later? No, It's something about the 3.3 regulator, that is handling a lot of amperage from the 5100.. I thought I saw somewhere on another instructable, someone solved the problem (slightly) by DOUBLING the regulator. (stacking another one on top of the original, so you had 2 in parallel.) <https://www.instructables.com/id/Beef-up-your-Arduino-power/>
